

# Code optimization

Module 5

Code optimization improves the intermediate code.

→ Less space and time.

Code optimization techniques:

- 1) Common subexpression elimination.
- 2) Constant folding.
- 3) Copy propagation
- 4) Dead code elimination.
- 5) Code Motion
- 6) Induction Variable elimination and Reduction

These are common examples of such function-preserving or semantics-preserving transformations.

## Code optimization:-

Elimination of unnecessary instructions in object code, or replacement of one sequence of instructions by a faster sequence of instructions that does the same thing is usually called 'code improvement' or 'code optimizations'.

### Local code optimization:-

Code improvement within a basic block.

### Global code optimization:-

Mostly based on dataflow analyses.

## 1) Common sub-expression elimination

Common subexpression -

- i) if it was previously computed.
- ii) Values of Variables have not changed.

$$\begin{array}{|l|} \hline a = b + c \\ b = a - d \\ c = b + c \\ d = a - d \\ \hline \end{array} \rightleftharpoons \begin{array}{|l|} \hline a = b + c \\ b = a - d \\ c = b + c \\ d = b \\ \hline \end{array}$$

## 2) Constant folding

If the value of an expression is a constant, use the constant instead of expression.

$$\boxed{\text{PI} = \frac{22}{7}} \Rightarrow \boxed{\text{PI} = 3.14}$$

### 3. Copy Propagation

if  $f = g$  // copy statement.

use  $g$  for  $f$  after  $f = g$ .

Eg:-

$$\begin{array}{l} x=a \\ y=x*b \\ z=x*c \end{array}$$

$\Rightarrow$

$$\begin{array}{l} x=a \\ y=a*b \\ z=a*c \end{array}$$

### 4. Dead Code elimination

A variable is live, if its value can be used subsequently; otherwise it is dead.

$$\begin{array}{l} x=a \\ y=a*b \\ z=a*c \end{array}$$

$\Rightarrow$

$$\begin{array}{l} y=a*b \\ z=a*c \end{array}$$

here,  $x$  is a dead variable, as we're no longer using ' $x$ ' in the computations.

## 5. Code motion

→ moves code outside a loop.

```
while(i<10)
```

```
{
```

```
    x = y + z;
```

```
    i = i + 1;
```

```
}
```

// this statement not working based on the loop condition.

So can move outside.

```
x = y + z;
```

```
while (i<10)
```

```
{
```

```
    i = i + 1;
```

```
}
```

## 6. Induction Variables and Reduction in Strength:

A Variable 'x' is said to be an 'induction variable' if there's a positive or negative constant  $c$  such that each time  $x$  is assigned, its value increases by  $c$ .

The transformation of replacing an expensive operation by cheaper one, is known as Strength reduction.

(multiplication can be replaced by addition)

Eg:-

```
i = 1;  
while (i < 10)  
{  
    t = i * 4;  
    i = i + 1;  
}
```

$\Rightarrow$

```
t = 4;  
while (t < 40)  
{  
    t = t + 4;  
    i = i + 1;  
}
```

## Loop optimization

Most execution time of a programs is spent on loops. Decreasing the no. of instructions in an innerloop improves the running time of a programs.

## Loop optimization techniques:

1. Code motion.
2. Induction variable elim & reduction is strength.
3. Loop unrolling
4. Loop Jamming.

### 3. Loop unrolling

Duplicates the body of the loop multiple times, in order to decrease the number of times the loop condition is tested.

```

for(i=0; i<100; i++)
{
    display();
}

```

```

for(i=0; i<50; i++)
{
    display();
    display();
}

```

#### 4) Loop Jamming /merging

combines the bodies of 2 adjacent loops that would iterate the same no. of times.

```

for(i=0; i<100; i++)
{
    a[i] = 1;
}

for(i=0; i<100; i++)
{
    b[i] = 2;
}

```

```

for(i=0; i<100; i++)
{
    a[i] = 1
    b[i] = 2;
}

```

## Peephole optimization

This technique is applied to improve the performance of program by examining a short sequence of instructions in a window (peephole) and replace the instructions by a faster or shorter sequence of instructions.

### Peephole optimization techniques:

#### 1) Redundant Instruction Elimination

Eg:-  $\text{Mov } R_0, x$   
 $\text{Move } x, R_0$   $\rightarrow$  this code part is redundant.

But if it's labelled as  $L_1 : \text{Mov. } R_0, x$   
 $L_2 : \text{Mov } x, R_0$ .

We can't say that this code is redundant. It may execute at some other time.

## 2) Unreachable code elimination

$x = 0;$  ; already initialized  $x$  as 0.  
if ( $x == 1$ ) } So this block is  
{  
  {  
     $a = b;$   
  }  
}  
} ;  
{  
   $a = b;$   
}  
}  
; ;

So we can change the code into optimized code as:

```
 $x = 0;$   
if  $x == 1$  goto L1  
goto L2  
L1 :  $a = b;$   
L2 :
```

```
 $x = 0$   
if  $x \neq 1$  goto L2  
.  $a = b;$   
L2 :  
     $\leftarrow$  jump to L2.
```

removing unwanted goto's.

So  $a = b$  is unreachable.

So can safely remove.

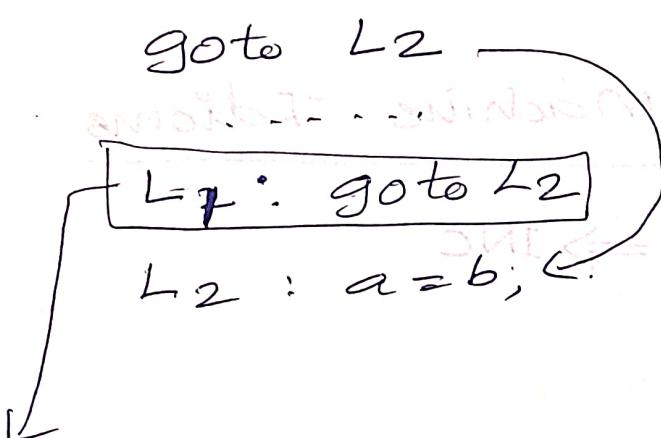

### 3) Flow-of-control optimization

Eg:  $\text{goto } L_1$

$L_1 : \text{goto } L_2$

$L_2 : a = b;$

We can rewrite it as

jump to  $L_2$ :  
perform  $a = b$ .

If this statement is not a target of any other statement, then this can be removed.

### 4) Algebraic simplifications

$x = x + 0$       } these codes will not change  
 $x = x * 1$       } the value of  $x$ ; so  
can be removed.

Reduction in strength

$$x^{12} \Rightarrow x * x$$

$$2 * x \Rightarrow x + x$$

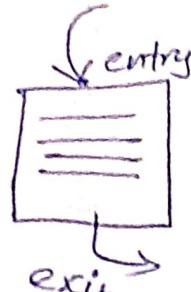

$$x * 2 \Rightarrow x \ll 1$$

$x * 2^1 \Rightarrow x \ll 1$        $x * 4 \Rightarrow x \ll 2$   
 left shift  
 $x / 2 \Rightarrow x \gg 1$        $x / 4 \Rightarrow x \gg 2$   
 right shift

## 5) Use of Machine Idioms

$i = i + 1 \Rightarrow \text{INC}$

# Basic Blocks and flow graphs.

- A basic block is a collection of sentences which are executed in sequential manner.
- Any basic block must contain one entry and exit points.
- Any basic block should not contain conditional or unconditional statements in the middle of the block.
  - conditional  $\rightarrow$  if, if-else, for, while...
  - unconditional  $\rightarrow$  break, continue, go-to, ...

$$x = a + b + c$$

$$t_1 = a + b$$

$$t_2 = t_1 + c$$

$$x = t_2$$

converted to 3 Address code.

## Flow graphs

1.  $PROD = 0$  → 1st stmt is a leader.
2.  $I = 1$  → 2nd stmt is a leader.
3.  $T_2 = \text{addr}(A) - 4$  → 3rd stmt is a leader.
4.  $T_4 = \text{addr}(B) - 4$  → 4th stmt is a leader.
5.  $T_1 = 4 * i$  → target of conditional or unconditional jump.
6.  $T_3 = T_2 [T_1]$
7.  $PROD = PROD + T_3$
8.  $I = I + 1$
9.  $\text{IF } I \leq 20 \text{ go to (5)}$
10.  $j = j + 1$
11.  $k = k + 1$
12.  $\text{IF } j \leq 5 \text{ goto (7)}$
13.  $i = i + j$  → statement following cond. or unconditional jump is a leader.

statements at beginning

$$24 + 20 = 30$$

$$dR = p$$

$$s + p = s$$

$$s = 20$$

$PROD = 0$

$I = 1$

$T_2 = \text{addr}(A) - 4$

$T_4 = \text{addr}(B) - 4$

$T_1 = 4 * i$

$T_3 = T_2 [T_1]$

$PROD = PROD + T_3$

$I = I + 1$

IF  $I \leq 20$  goto (5)

$j = j + 1$

$K = K + 1$

Flow graph

corresponds to following steps

## Example 2

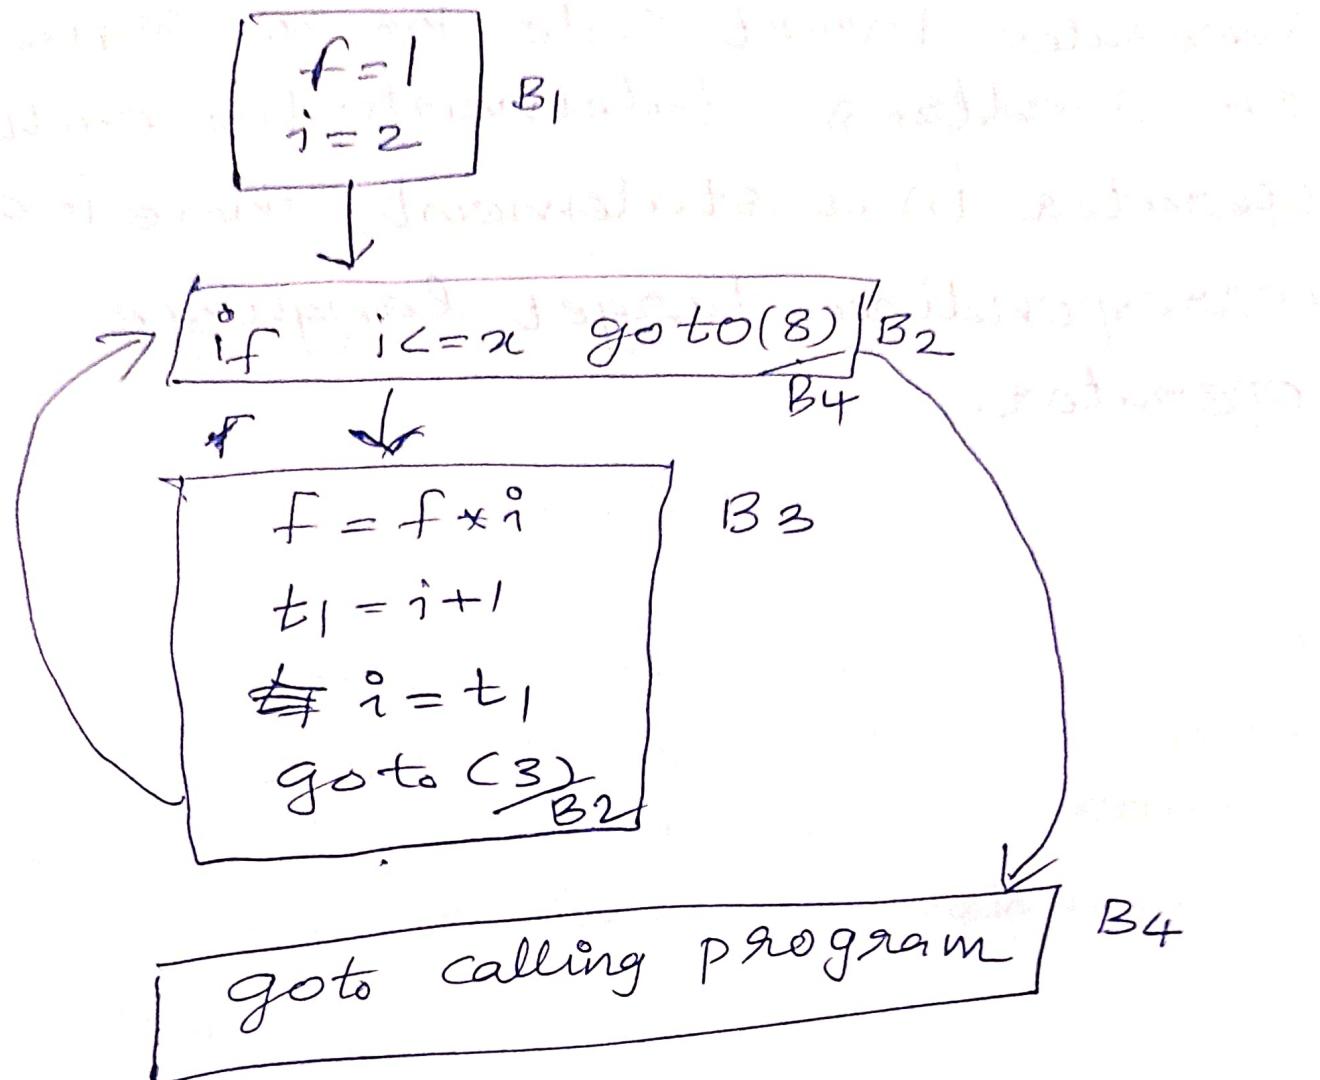

Consider the programs fragment:

```
fact(x)
{
    int f=1;
    for(i=2; i<=x; i++)
        f = f*i;
    return(f);
}
```

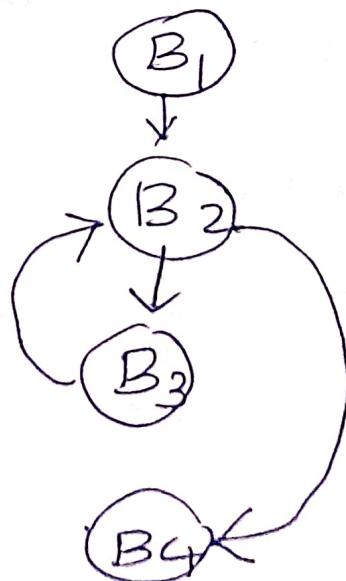

## 3-Address Code

```
1  f=1
2  i=2
3  if i<=x goto(8)
4  F=f*i
5  t1=i+1
6  i=t1
7  goto(3)
8  goto calling program.
```

leader stmts  $\rightarrow$  1, 3, 4, 8

Flow graph

# The Target Language.

The target computer models a 3AC machine with load and store operations, computation operations, jump operations, and conditional jumps.

The computer is a byte-addressable machine with n-general purpose registers,  $R_0, R_1 \dots R_{n-1}$ .

We assume the following kinds of instructions are available.

1) Load operations:

LD dst,addr

2) Store operations:

ST x,r

3) Computation: Operations of the form

OP dst,src<sub>1</sub>,src<sub>2</sub>

where OP is the operator, src<sub>1</sub> and src<sub>2</sub> are the locations.

Eg:- SUB r<sub>1</sub>, r<sub>2</sub>, r<sub>3</sub>

Computes r<sub>1</sub> = r<sub>2</sub> - r<sub>3</sub>.

→ Unary operators that take only one operand do not have a src<sub>2</sub>.

#### 4) Unconditional jumps:-

BR L

Causes control to branch to the machine instruction with label L.  
(BR stands for Branch)

#### 5) Conditional jumps:-

It is of the form Bcond n L,

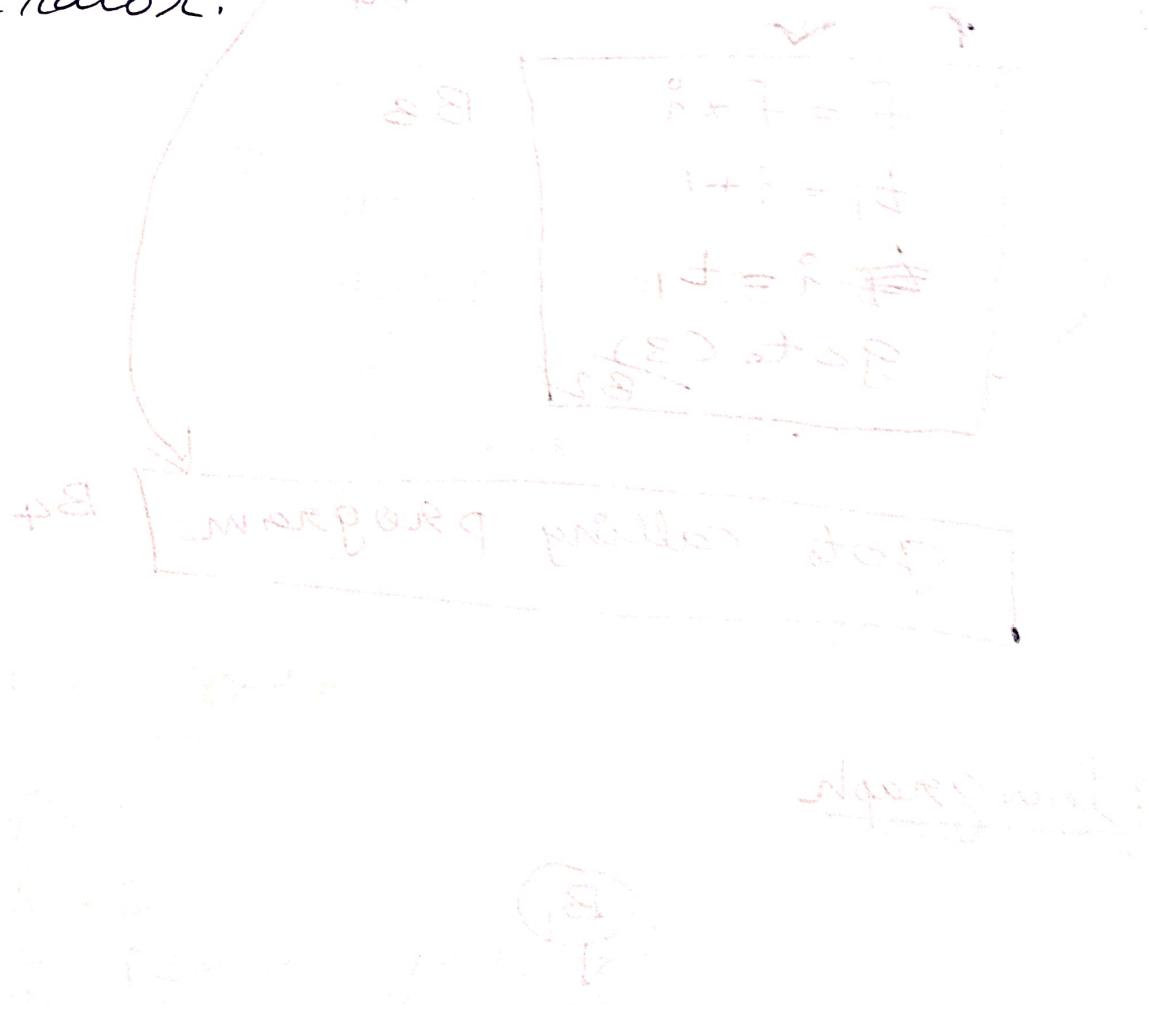

where 'n' is a register, L is a label, and 'cond' stands for any of the common tests on values in the register n.

Eg:- BLTZ r, L

It causes a jump to label L if the value in register r is Less Than Zero. and allows control to pass to the next machine instruction if not.

## A simple code generator

- Generates target code for a sequence of 3-address statements. For each operator in a statement, there is a corresponding target language operator.

## A simple code generator

- Generates target code for a sequence of 3-address statements. For each operator in a statement, there is a corresponding target language operator.

# Register and Address Descriptors

## 1. Register Descriptor:

keeps track of what currently in each register. Initially all registers are empty.

## 2. Address Descriptor:

keeps track of the location where the current value of the name can be found. Location may be register, a stack location or memory address.

## A Code Generation Algorithm

For a three-address instruction such as  $x = y \text{ op } z$ , do the following:

- ① Use getReg ( $x = y + z$ ) to select registers for  $x, y$  and  $z$ . Call these  $R_x, R_y$  and  $R_z$ .

② If  $y$  is not in  $Ry$  (according to the register descriptor), then issue an instruction  $LD Ry, y'$ , where  $y'$  is one of the memory locations for  $y$  (according to the address descriptor)

③ similarly, if  $z$  is not in  $Rz$ ,

$LD Rz, z'$

④ Issue the instruction  $ADD Rx, Ry, Rz$ .

Eg:-

$$d = (a - b) + (a - c) + (a - c)$$

### 3-address code

$$t_1 = a - b$$

$$t_2 = a - c$$

$$t_3 = t_1 + t_2$$

~~$$d = t_3 + t_2$$~~

R<sub>0</sub>, R<sub>1</sub>

statement	Code generated	R-D	A-D
$t_1 = a - b$	MOV A, R <sub>0</sub> SUB B, R <sub>0</sub>	Reg. are empty R <sub>0</sub> contains t <sub>1</sub>	t <sub>1</sub> in R <sub>0</sub>
$t_2 = a - c$	MOV A, R <sub>1</sub> SUB C, R <sub>1</sub>	R <sub>0</sub> cont. t <sub>1</sub> R <sub>1</sub> cont. t <sub>2</sub>	t <sub>1</sub> in R <sub>0</sub> t <sub>2</sub> in R <sub>1</sub>
$t_3 = t_1 + t_2$	ADD R <sub>1</sub> , R <sub>0</sub>	R <sub>0</sub> Cont. t <sub>3</sub> R <sub>1</sub> cont. t <sub>1</sub>	t <sub>2</sub> in R <sub>1</sub> t <sub>3</sub> in R <sub>0</sub>
<del><math>d = t_3 + t_2</math></del>	ADD R <sub>1</sub> , R <sub>0</sub> MOV R <sub>0</sub> , d	R <sub>0</sub> cont. d	d in R <sub>0</sub>

ST d, R<sub>0</sub>; if 'd' is a global variable.

## Example

$$x = (a - b) + (a + c)$$

3AC

$$t_1 = \cancel{a+c}$$

$$t_2 = a+c$$

$$t_3 = t_1 + t_2$$

$$DC = t_3$$
